

Predicting Population for Male of Rural Area in Bangladesh

Rafiqul Islam

University of Rajshahi

Abstract. In this paper the population for male of rural area in Bangladesh is predicted by using the geometric growth rate method. The predictions are computed in a three-steps procedure. In the first step, the predictions are computed using an exponential model estimated by Quasi-Newton method for the years 1974, 1981, 1991 and 2001 using the package STATISTICA. Using the cross-validation predictive power (CVPP) criterion and coefficient of determination, the shrinkage coefficient (λ) is constructed. The shrinkage coefficient determines the adequacy of the first step prediction. In the second step, these predicted values are used to estimate the growth rate for different age groups by using the geometric growth rate method. In the final step, considering the population for male of rural area in Bangladesh for the census year 2001 as the base population and using the estimated geometric growth rate of the second step estimation, the predictions for the male population of rural area of Bangladesh are estimated for the years 2002 through 2031 by applying geometric growth rate method.

Keywords. male rural population; exponential model; geometric growth rate method; cross-validity predictive power (CVPP); coefficient of determination; shrinkage; F -test.

1 Introduction

It is noted that Bangladesh is a rural predominant country. Moreover, Bangladesh is a poor country and mostly dependent on foreign aid and relief. Most of the people of Bangladesh reside in rural area of which more than fifty are male. Rural people of Bangladesh always struggle for survival. It should be mentioned here that rural families are much more dependent on male earnings than that of urban. Generally the rural people of Bangladesh are hard hit financially in comparison to the urban people because of shortage of income generated by the activities in rural region. As a consequent, there is a trend of people, particularly for male population, moving from rural area to urban areas of Bangladesh for better welfare. Since the independence in 1971, the population of Bangladesh is rising rapidly with accelerated growth rate in accordance with its areas. It is noted that Bangladesh is an agrarian based country and in fact, it is happened largely in rural areas. Male people in the rural areas generally migrate to urban areas for better job and other good facilities of livelihood. As a consequence, the heavy influx of people in the urban areas is a burden to the government of Bangladesh for various reasons, e.g. lack of shelter, education, health, clean water, etc. For this reason, government of Bangladesh should gather proper information of the population in rural areas in near future, middle future, far future population so that it can take proper steps in income generating activities for the rural population especially male population. Consequently, the government of Bangladesh needs firm and rigid policy to accommodate its fast growing rural male population so that government can provide the necessary requirements to its citizens and hence the pressure of urbanization would be abated. That is why the stream of migration from rural to urban area would be slow down.

Since the pattern of age structure of the population differs for various demographic variables, from country to country, and from region to region. Islam et al. (2003) found that the age structure for male population of Bangladesh follows a modified negative exponential model. And the age structure for the population of both sexes and female of Bangladesh follows a modified negative exponential model (Islam, 2003 and 2005). It is noted that various types of model might be used to predict the population. Among them are linear model, geometric growth model, exponential growth model, modified exponential model, logistic model, Makeham model, Gompertz model, polynomial model, etc.

The objective, in this paper, is to provide proficient prediction of the population for male of rural areas in Bangladesh for the years 2002 to 2031 using the most recent data and the geometric growth rate method for different age groups by a three step procedures. These predictions can then be used for improve-

ment of government's rural infrastructural policy decisions and job creating function.

This paper is organized as follows. The data sources of this study are presented in section 2. Section 3 describes the models, methodological issues and various tests. Empirical results and discussion of the results are reported in section 4. Finally, section 5 includes the conclusion of the paper.

2 Data Sources of this Study

To fulfill the objective of this paper the secondary quinquennial age data on the population for male of rural area of Bangladesh have been taken from various issues (Bangladesh Bureau of Statistics, 1977, 1984, 1994, and 2003) of Bangladesh population census. It is to be noted that the population census in Bangladesh occurs in every ten years distant and the latest census took place in 2001. Using the latest two census data of 1991 and 2001 the predictions for the years 2002 through 2031 are computed. The age group considered in this study are (0-4, 5-9, 10-14, 15-19, . . . , 65-69, 70 and above). The population values which are counted in thousands are shown in Table 1.

3 Models, Methodological Issues, and Various Tests

3.1 Data Smoothing Technique

The data of the current study have been smoothed out to eliminate any anomalies from the age related population data. The method used to smooth the data is the "4253H twice" (Velleman, 1980). This is the default in the Minitab package – version 12.1. The smoothed data are then used to fit an exponential model for the years 1974, 1981, 1991, and 2001 separately. The smoothed data are given in Table 1.

3.2 The Models

Using the scattered plot of ages and smoothed age structure for male population in rural area of Bangladesh (Figure 1), it is observed that population is distributed with a negative exponential distribution with respect to ages. Therefore, a two-parameters negative exponential model is considered and the mathematical structure of the model is

$$y = e^{(-ax+b+u)},$$

where, x represents mean value of the age group; y represents male population; a , b are unknown parameters and u is the disturbance term of the model. Note

Table 1. Observed, smoothed, and predicted male population by age group in rural area of Bangladesh during 1974-2001 censuses.

| Age group | 1974 | | | 1981 | | |

| Total | 43427 | 43034 | 42616 | 48462 | 48324 | 48436 |

that these models have been estimated using the software STATISTICA. The predicted values of these models are also given in Table 1.

The most important properties of the negative exponential model are given below:

- The domain of the negative exponential model is real numbers;
- The range of this model is positive values, that is, it is always greater than zero;
- The graph of the negative exponential model is decreasing;
- The graph of this model is asymptotic to the x -axis when x approaches positive infinity;
- The graph is continuous and smooth.

It should be mentioned here that other usual models such as linear, loglinear, semi-loglinear, logistic, quadratic, cubic, Gompertz, and Makeham models are also tried to be applied to fit this data aggregate. But, these models performed very poorly due to their shrinkage coefficients, coefficients of determination and the lack of significance of the model parameters for this data

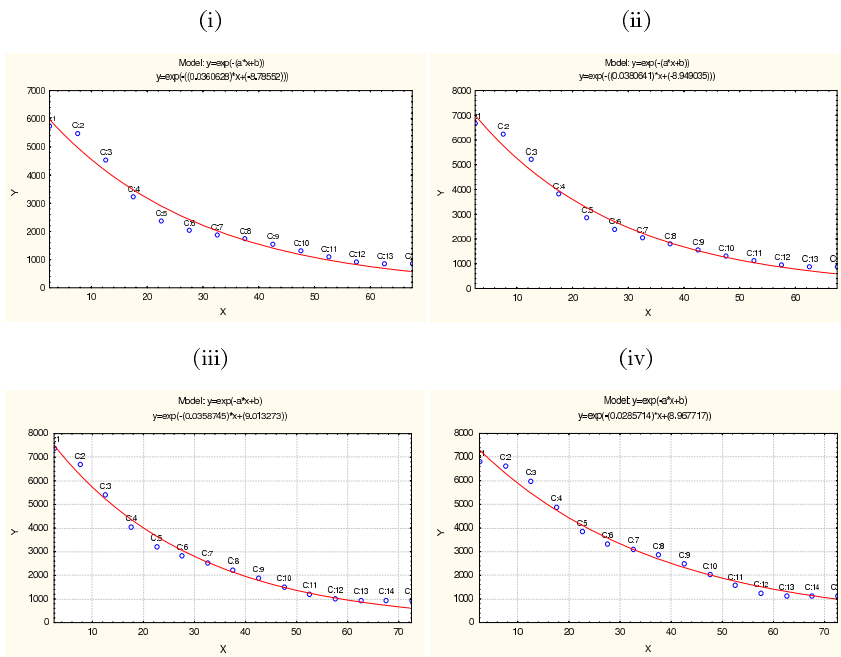

Figure 1. Observed and fitted male population in rural area of Bangladesh in (i) 1974, (ii) 1981, (iii) 1991, and (iv) 2001.

in this study. As a consequent, the findings of these models are not shown here.

3.3 Geometric Growth Rate Method

Geometric growth rate is estimated by using the following equation

$$\hat{P}_{t_2}^{m-m+5} = \hat{P}_{t_1}^{m-m+5} \{1 + r^{m-m+5}\}^{t_2-t_1}, \quad (1)$$

where, $\hat{P}_{t_1}^{m-m+5}$ is the predicted initial population at time t_1 for the age interval m to $m + 5$; $\hat{P}_{t_2}^{m-m+5}$ is the predicted terminal population at time t_2 for the age group m to $m + 5$; r^{m-m+5} is the intercensal annual growth rate of the age interval m to $m + 5$; $(t_2 - t_1)$ is the time distance between intercensal periods, and m is the lower limit of each age group. The intervals are counted as $[m, m + 5)$.

The r^{m-m+5} is computed for different age groups from (1) as in the following,

$$r^{m-m+5} = \text{Antilog} \left[\left(\frac{1}{t_2 - t_1} \right) \log_e \left(\frac{\hat{P}_{t_2}^{m-m+5}}{\hat{P}_{t_1}^{m-m+5}} \right) \right] - 1. \quad (2)$$

Years 1991 and 2001 are considered as the initial and the terminal populations respectively in estimating the age specific growth rates by equation (2).

For prediction purpose, the year 2001 census is treated as the base population. The intercensal annual growth rate, at different ages, during 1991-2001 is used in this study assuming fertility and mortality remain constant during the forecast period. Estimates of the intercensal annual geometric growth rate for different age groups are computed based on the first-phase predicted population for the census years 1991 and 2001.

3.4 Model Validation

Model assessment criteria used are the usual regression t -test, and R^2 . For model validation, the cross-validation predictive power (CVPP) denoted by ρ_{cv}^2 , is computed by $\rho_{cv}^2 = 1 - \frac{(n-1)(n-2)(n+1)}{n(n-k-1)(n-k-2)} (1 - R^2)$, where n is the number of classes, k is the number of regressors in the model, and R^2 is the coefficient of determination in the first stage of estimation. The shrinkage coefficient of the model is equal to the absolute value of $\lambda = (\rho_{cv}^2 - R^2)$, (Stevens, 1996). Closer the value of λ tends to zero, then the prediction is better. Furthermore, the stability of R^2 of the model is equal to $(1 - \text{shrinkage coefficient})$. The estimated CVPP's corresponding to their R^2 and information on model fittings are launched in Table 2.

Table 2. Information on model fittings and CVPP.

| Model | n | K | R^2 | ρ_{cv}^2 | Shrinkage | Cal. F | Tab. F (at 1% level) |
|-------|-----|-----|---------|---------------|-----------|----------|------------------------|
| 1 | 14 | 1 | 0.96992 | 0.961912 | 0.008008 | 303.0599 | 9.33 with (1, 12) d.f. |
| 2 | 14 | 1 | 0.98160 | 0.976701 | 0.004899 | 640.1739 | 9.33 with (1, 12) d.f. |
| 3 | 15 | 1 | 0.98772 | 0.984718 | 0.003002 | 1045.63 | 9.07 with (1, 13) d.f. |
| 4 | 15 | 1 | 0.98344 | 0.9794 | 0.00404 | 772.0242 | 9.07 with (1, 13) d.f. |

3.5 F -test

To investigate the overall measure of model significance as well as the significance of R^2 , the F -test is applied to the fitted model. The mathematical formula for F -test is given by

$$F = \frac{\frac{R^2}{p-1}}{\frac{1-R^2}{n-p}} \quad \text{with } (p-1, n-p) \text{ degrees of freedom (d.f.),}$$

where p is the number of parameters to be estimated in the model, n is the number of cases and R^2 is the coefficient of determination in the model (Gujarati, 1998).

4 Empirical Results and Discussion of the Results

Both the smoothed and the original data series are used to fit negative exponential model for the years 1974, 1981, 1991, and 2001 for all age groups. It is found that the smoothed data has better predictions. Consequently, the smoothed series have been used in the first phase prediction. The estimated models for the male population of rural area are given in the following forms:

(a) $y = \exp\{-0.03606x + 8.78552\}$ in 1974

| | | |
|----------------|-----------|---------|
| $t(12)$ -stats | 15.08302 | 240.832 |
| p -value | (0.00000) | (0.000) |

with coefficient of determination $R^2 = 0.96992$ and $\rho_{cv}^2 = 0.961912$.

(b) $y = \exp\{-0.03806x + 8.949\}$ in 1981

| | | |
|----------------|-----------|---------|
| $t(12)$ -stats | 19.15078 | 308.453 |
| p -value | (0.00000) | (0.000) |

providing $R^2 = 0.98160$ and $\rho_{cv}^2 = 0.976701$.

(c) $y = \exp\{-0.03587x + 9.0133\}$ in 1991

| | | |
|----------------|-----------|----------|
| $t(13)$ -stats | 25.09937 | 342.8943 |
| p -value | (0.00000) | (0.000) |

giving proportion of variance explained $R^2 = 0.98772$ and ρ_{cv}^2 is 0.984718.

(d) $y = \exp\{-0.02857x + 8.9677\}$ in 2001

| | | |
|----------------|-----------|----------|
| $t(13)$ -stats | 22.78804 | 371.8038 |
| p -value | (0.00000) | (0.000) |

providing coefficient of determination $R^2 = 0.98344$ and $\rho_{cv}^2 = 0.9794$.

The estimated CVPP, ρ_{cv}^2 's, corresponding to their R^2 are shown in Table 2. From this table it appears that all the fitted models (a)-(d) are highly cross-validated and their shrinkage coefficients are 0.008008, 0.004899, 0.003002 and 0.00404, respectively. These imply that the fitted models (a)-(d) stability is more than 96%, 97%, 98% , and 97%, respectively. Moreover, it is found that the parameters of the fitted models (a)-(d) are highly statistically significant with significance of variance explained. The stability of R^2 for these models is more than 99%.

The calculated values of F -test for the models (a)-(d) are 303.0599 with (1, 12) d.f., 640.1739 with (1, 12) d.f., 1045.63 with (1, 13) d.f., and 772.0242 with (1, 13) d.f., respectively, whereas the corresponding tabulated values of the models (a)-(b) are only 9.33 but for the models (c)-(d) is only 9.07 at 1% level of significance, respectively. Therefore, from these statistics it is seen that these models and their corresponding R^2 's are highly statistically significant.

The predicted values for the census years 1991 and 2001 are then used to estimate the geometric growth rates for each age group, which, in turns, are used to predict the population for male of rural area for the years 2002 to 2031 considering the observed population of 2001 census as base year population. The estimated geometric growth rate for each age group is provided in Table 3.

Table 3. Estimated geometric growth rate for male population of rural area in Bangladesh at each age group.

| Age group | The estimated geometric growth rate |
|-----------|-------------------------------------|
| 0-4 | -0.002723971 |
| 5-9 | 0.000920627 |
| 10-14 | 0.004576593 |
| 15-19 | 0.008264377 |
| 20-24 | 0.011949181 |
| 25-29 | 0.015638680 |
| 30-34 | 0.019363645 |
| 35-39 | 0.023070797 |
| 40-44 | 0.026830691 |
| 45-49 | 0.030572554 |
| 50-54 | 0.034361556 |
| 55-59 | 0.038142874 |
| 60-64 | 0.042014927 |
| 65-69 | 0.045725582 |
| 70+ | 0.049682362 |

Using these estimated age specific growth rates and 2001 census observed population as the base, the population for male of rural area is predicted for the years 2002 through 2031 which is given in the Table 4.

Table 4. Predicted rural male population (in thousands) of Bangladesh during 2002-2021 (in thousands).

The rate at which the population for rural male is growing is a concern for the government of Bangladesh. The government of Bangladesh requires policies to provide the maximum welfare to its citizens of the rural areas. In essence, the government needs strategic plan to provide good health care, satisfactory accommodation, roads and highways, available educational institutions, and

secured jobs to satisfy the minimum needs for the people of the rural area of Bangladesh so that the tendency of people from rural area to urban area would be abated. And henceforth, the pressure of urbanization would be reduced, that is expectation to our nation.

5 Conclusion

This study observed that the age pattern of the rural male population of Bangladesh follows a two-parameters negative exponential model for the census years 1974, 1981, 1991, and 2001. The smoothed data are then used to estimate the geometric growth rate following Malthusian law of population growth. This projected population is an early warning to the government of Bangladesh to take the matter serious in accommodating its rural citizens with maximum welfare in the future. Although the negative exponential models are used for the first phase predictions, there are a number of other models that can be applied to fit the data, e.g., logistic, quadratic, cubic, Gompertz, and Makeham models. However, these models performed poorly in accordance with their shrinkage coefficients in this study. Therefore, these were omitted from the analysis. The research can be further explored to investigate the district wise comparison of population growth of Bangladesh. In fact, the most densely populated districts e.g. Dhaka, Chittagong, Rajshahi, Sylhet, Barisal and Khulna are kept in our next research agenda for analysis.
